Position Paper of the Pigment and Filler Industry in the Nano Discussion

status: November 2015

The Recommendation of the EU Commission on the Definition of Nanomaterial has major impacts on pigments and fillers: because a lot of colour pigments and fillers currently on the market fall under this definition and, consequently, under nano-specific regulation – even though these pigments and fillers have been in use for a very long time.

Pigments and fillers serve for the colouring and surface structuring of numerous daily life objects. They consist of small particles which are insoluble and firmly bound in the application medium. Pigments and fillers are nothing new. They have been in existence for many centuries, e.g. in rock and cave paintings. Today, pigments and fillers are found in a wide range of applications from automobile paint to bricks.

Definition and measurability

According to the Commission Definition^[1] the particle size (1-100 nm) is the decisive criterion for a nanomaterial. The inclusion of aggregates and agglomerates turns many pigments and fillers into nanomaterials per definition – while concrete requirements are lacking for how to verify this in practice. Since the publication of the Definition in the year 2011, public authorities and the stakeholder industries have been searching intensively for a straightforward and workable solution in order to enable a decision on whether there is a nanomaterial or not. Building on long-standing expertise in the pigment and filler industry, we demonstrated in a project together with the Joint Research Centre (JRC) in Ispra that no universally accepted method exists for making this decision.^[2]

Hazard profile of pigments and fillers

Toxicity

Like for all powder form substances, inhalation is the toxicologically relevant uptake route for pigments and fillers. This is relevant for industrial workplace exposure. By way of technical and organisational protective measures, inhalation of pigments and fillers is reduced to a minimum in production and processing. Another possibility for reducing dust exposure in processing is the use of ready-made dispersions.

It is frequently claimed that after their uptake in the body, agglomerates or aggregates might release individual nanoparticles. More recent studies in this area indicate that there is no disintegration of aggregates or agglomerates – with a release of nanoparticles – in the lungs.

^[1] According to the Commission Definition, a nanomaterial is described as „a natural, incidental or manufactured material containing particles, in an unbound state or as an aggregate or as an agglomerate and where, for 50 % or more of the particles in the number size distribution, one or more external dimensions is in the size range 1 nm - 100 nm.”

^[2] JRC Technical Reports „ Basic comparison of particle size distribution measurements of pigments and fillers using commonly available industrial methods“ <http://publications.jrc.ec.europa.eu/repository/handle/JRC92531>

The attractive forces between the particles are too strong for their breaking up, e.g. in the lung fluid.^[3]

In comprehensive testing regarding toxicity of nanomaterials^[4] so far there has been no indication of nano-specific toxicity. Thus, for classic materials like pigments and fillers, which have been on the market for a long time, the assessment of hazards concerning safety and environment does not change fundamentally – simply because today many of these materials need to be deemed nanomaterials.

Studies on the release of nanomaterials

Release from paints and plastics

Numerous studies (e.g. the study FRiNano^[5]) showed that in particular pigments and fillers that were firmly bound in a matrix did not release any free nanoparticles, not even under mechanical stress or weathering. For this reason, it makes no sense to address such firmly bound pigments and fillers in connection with nano.

Migration of nanoparticles from consumer articles

Pigments and fillers are frequently used in plastics, coatings and printing inks that come into contact with food. Here, it must be ensured that there is no migration to the foodstuff.

Based on studies on migration from plastics^[6,7] and on theoretical considerations^[8,9] it was possible to demonstrate that particle migration can be excluded for particles sized over 2 to 3 nm. No migration of nanomaterials was observed in relevant studies with printing inks, either.^[10]

Consequently, also in these respects we see no basis for special restrictions by the legislator for nanomaterials.

More transparency could be brought about by informing consumers about nanomaterials not being linked with higher risk generally.

REACH and Nano

We concur with the statement made by the EU Commission in the so-called *Second Regulatory Review on Nanomaterials*^[11] that “REACH sets the best possible framework for the risk management of nanomaterials”.

The ideas on future requirements to nanomaterials, as they have been discussed inside the EU Commission so far, are not justified from our viewpoint. They go far beyond the current requirements to substances already placed or being available on the market. In the least favourable case, this would lead to a withdrawal of many products in Europe.

Nanoproduct register

We reject a “nanoproduct register” in general, both nationally and in Europe.

The necessary transparency and information about substances are provided under the REACH and CLP Regulations: Irrespective of the nano-property, substances are examined as to their hazards as a matter of principle.

Transparency at product level should be created by means of various product-specific pieces of regulation – with all of them having a uniform definition that would prevent the same substance being deemed “nano” under one set of rules and “not nano” under another. This would also enhance consumer safety and transparency.
